Report on shipping accidents in the Baltic Sea area for the year 2008

Introduction

Reports on shipping accidents in the Baltic Sea area have been compiled since 2000. In 2004 a new reporting format was developed and used for the reporting of accidents starting 2004. For that reason the data for 2003 and the subsequent years are not fully comparable. The changed reporting is interpreted as a reason for the increased number of accidents in 2004 and subsequent years, when compared to 2003.

All Contracting States have provided data on shipping accidents for 2008. According to the agreed procedure all accidents (including but not limited to grounding, collision with other vessel or contact with fixed structures (offshore installations, wrecks, etc.), disabled vessel (e.g. machinery and/or structure failure), fire, explosions, etc.), which took place in territorial seas or EEZ of the Contracting Party and involved tankers over 150 GT and/or other ships over 400 GT irrespectively if there was pollution or not are reported.

Ship traffic in the Baltic

IMO regulations require Automatic Identification System (AIS) transponders to be fitted aboard all ships of 300 gross tonnage and upwards engaged on international voyages, cargo ships of 500 gross tonnage and upwards not engaged on international voyages and all passenger ships irrespective of size. The AIS enables the identification of the name, position, course, speed, draught and cargo of ships and displays all available data over a common background map.

The traffic statistics presented below has been generated by the HELCOM AIS database.

To get a full picture of the shipping safety in the Baltic, basic information on the intensity of shipping is of importance. According to the HELCOM AIS, there are about 2,000 ships in the Baltic marine area at any given moment, and each month around 3,500–5,000 ships ply the waters of the Baltic. The intensity of traffic can also be illustrated by the number of ships crossing the pre-defined HELCOM AIS lines as presented in Figures 1 and 2 (ships according to the type of vessels and their draught, respectively). A snapshot illustrating the spatial distribution of shipping activities in the whole Baltic at a specific moment can be seen in Figure 3 and images of the traffic on the Baltic Sea based on AIS signal within time periods of two days and one week are shown in Figures 4 and 5. The numeric data behind maps in Figures 1 and 2 are presented in Tables 1 and 2.
Figure 1. Number of ships crossing AIS fixed lines in the Baltic Sea according to the type of the vessels, 2008.
Figure 2. Number of ships crossing AIS fixed lines in the Baltic Sea according to the draught, 2008.
Figure 3. Snapshot of ship traffic in the Baltic Sea on 8 April 2009. Note: the yellow dots illustrate AIS stations and the arrowheads depict different types of ships and direction of travel.

Figures 4 and 5. The figure on the left illustrates cargo, tanker and passenger ship traffic on the Baltic Sea during two days in November 2008. The figure on the right shows the density of shipping traffic during one week in 2008, with the busiest routes highlight in yellow.

*) For ships passing the Drogden the maximum draught is 8 m; therefore these numbers are probably due to a reporting error.
HELCOM AIS has been in operation since July 2005 providing additional information for the analysis of each individual accident case by respective Contracting States and the findings of such investigations are discussed during meetings of HELCOM groups with a view to identifying the possible need and possibilities of HELCOM actions in this area.

The HELCOM AIS historical statistics on ship traffic allow for the assessment of annual changes in traffic intensity. Since 2006, HELCOM has been following the trends in vessel traffic crossing fixed AIS lines, and a rising trend in number of crossings is clear (Figure 6 and Table 3). Although ship traffic is increasing (and is expected to continue doing so), a part of the increase in numbers could also be explained by the growing number of vessels registered in the AIS system.

Table 3. Number of ships crossing fixed AIS lines in the Baltic Sea during 2006-2008.

### Overview of accidents in the Baltic Sea

According to the reports from the Contracting States there were 135 ship accidents in the HELCOM area in 2008 (Figure 7), which is 15 more than the year before (increase by 12.5%) and 18 more than in 2006 (increase by 15%). The rising number of accidents could be explained by 20% increase in ship traffic between 2006 and 2008. In one case, the reporting Contracting Party did not provide information about whether the accident resulted in pollution or not.

![Number of reported accidents in the Baltic Sea during the period 2000-2008](image)

**Figure 7**

The spatial distribution of the reported accidents in 2008 is presented in Figure 8. As can be noted, almost all accidents occurred very close to shore or in harbours.
HELCOM
Shipping accidents in the Baltic Sea during 2008

- Accidents in 2008
- Total number of accidents: 135
- Data by: DE, DK, EE, FI, LV, LI, PL, RU and SE

**Figure 8**
Groundings were the most common type of accident in the Baltic accounting for almost half of all reported cases (44%), while a third of reported accidents were collisions (30%) (Figure 9). Since 2006, the share of groundings has increased (from 39%) and the share of collisions has decreased (from 46%). These proportions have not changed significantly since 2007, however, when 45% of reported accidents were groundings and 33% collisions. On the other hand, there were nine accidents in 2008 classified as “pollution accident” type, not related to any grounding or collision, but occurring e.g. during fuel transfer – the most reported since 2000 and a significant increase compared to none in 2006 and 2007. One of these accidents was related to an oil spill on deck and no pollution at sea was reported.

![Types of accidents in the Baltic Sea during 2008](image)

**Figure 9**

The share of groundings and collisions in accidents in 2008 (Figure 9) is similar to their share in total number of accidents during 2000-2008 (Figure 10).

![Types of accidents in the Baltic Sea during the period 2000-2008](image)

**Figure 10**
Spatial distribution of different types of reported accidents in the Baltic Sea in 2008 is presented in Figure 11.
Types of vessels involved in the accidents

As can be seen from Figure 12, cargo vessels are the main group of ships involved in accidents (45%), followed by passenger vessels (18%) and tankers (10%). This proportion more or less reflects the amount of different vessel types making up the Baltic Sea traffic in 2008 (crossings through the AIS lines, see Table 1), except for passenger ships for which a higher risk can be observed - passenger ships made up 10% of the overall traffic while their share in accidents was as much as 20%.

![Types of ships involved in accidents in the Baltic Sea during 2008](image)

_Total number of ships involved in accidents: 152_
As tankers are often an issue of high concern, a map on accidents involving tankers from 2000 to 2008 (Figure 13) is also presented here. All tankers involved in accidents in 2008 were double hull ships.
Causes of accidents

Human factor was the main cause of accidents in almost half (47%) of the incidents reported in 2008. External and technical factors were the reason for 18% and 13% of accidents, respectively (Figure 14).

Figure 14

Only one accident was reported as occurring in ice conditions in 2008. On the other hand, for a number of accidents no information was provided on ice presence.
Spatial distribution of accidents with indication of the cause is presented in **Figure 15**.
Groundings

In 2008, there were 60 reported groundings – more than any other year since HELCOM reporting started (Figure 16). Accounting for 44% of the total number of reported accidents in 2008, groundings have been the most common type of accident in the Baltic since 2007, in contrary to 2005 and 2006 when collisions were more common.

Figure 16

Figure 17 illustrates the presence/absence of a pilot on board vessels in cases of grounding accidents in 2008. Clearly the vast majority (65%) did not have a pilot on board at the time of grounding. On the other hand, most reported groundings in 2008 (80%) occurred with vessels having a draught of less than 7 m (Figure 18).
The map of the reported groundings in 2000-2008 (Figure 19) clearly indicates that the areas of primary concern are:

- Danish straits
- Gulf of Finland
- Åland/Archipelago Sea area
- Swedish coast of the Baltic Proper
- Ports.

The other areas where groundings have occurred deserve the attention of the relevant states as well.

The map of groundings in 2008 (Figure 20) especially points to the Danish straits.
HELCOM
Groundings in the Baltic Sea during 2000-2008

- Grounding
- Total number of collisions: 414
- Data by: DE, DK, EE, FI, LI, LV, PL, RU, SE

Figure 19
Figure 20

HELCOM
Groundings in the Baltic Sea during 2008

- Grounding
Total number of groundings: 60
Data by: DE, DK, EE, FI, LI, LV, PL, RU, SE
The statistics on groundings in southwestern Baltic Sea, including the Danish straits, show an increase in recent years (Figures 21 and 22) accounting for around 58% of all groundings registered in 2000-2008. The peak year was 2007 when 37 grounding cases were reported, and in 2008 this number decreased by 5.

Figure 21

Grounding accidents in the southwestern Baltic Sea, 2000-2008

Figure 22

HELCOM
Groundings in southwestern Baltic Sea during 2000-2008
Groundings 2000-2008: 239
Total number of groundings: 415
Data by: DE, DK, EE, FI, LI, LV, PL, RU, SE
The number of the reported groundings in the Gulf of Finland doubled between 2007 and 2008 after a comparatively low number of incidents in the two prior years (*Figure 23*).

![Grounding accidents in the Gulf of Finland, 2000-2008](image_url)

**Figure 23**

**Collisions**

Amounting to 41 cases (30%) of all accidents in 2008 and 288 cases (32%) for the period 2000-2008; collisions are the second most frequent type of shipping accidents in the Baltic. The number of reported collisions has decreased in the last few years, however, with an increase in one, there was not much change in the number of incidents reported between 2007 and 2008 (*Figure 24*).

![Collisions in the Baltic Sea during 2000-2008](image_url)

**Figure 24**
Ship to ship collisions accounted for 39% of all collision cases in 2008 and the rest of the cases were collisions with fixed and/or floating structures, e.g. peers, navigation signs etc. On a positive note, the number of ship to ship collisions has almost halved since 2005-2006, whereas the number collisions with objects has remained largely unchanged (Figure 25).

Spatially collisions are not clearly accumulated in few areas (Figure 26) but the map of collisions during 2000-2008 (Figure 27) does point toward approaches to ports and the Danish straits as the most risky areas for ships to collide. No clear trend can be observed for collisions in the southwestern Baltic Sea, including the Danish straits (Figures 28 and 29) as the number of cases vary from year to year. Although there were two more collisions reported in the Gulf of Finland during 2008 than 2007, the number of incidents still remains dramatically lower than before 2006 (Figures 30 and 31).
More than one collision took place e.g. in Gothenburg, Szczecin, Gdansk, Gdynia, Klaipeda and St. Petersburg.
HELCOM
Collision accidents in the Baltic Sea during 2000-2008

- Collision

Total number of collisions: 288
Data by: DE, DK, EE, FI, LI, LV, PL, RU, SE

Figure 28

Figure 29
Collision accidents in the Gulf of Finland, 2000-2008

Figure 30

Figure 31
Accidents with pollution

As one may expect, accidents resulting in pollution get more attention of the competent authorities and media. According to the 2000-2008 data, 7% of the reported accidents ended up with some kind of pollution. In 2008, this percentage was the same, with nine out of the total 135 reported accidents resulting in pollution. One of these incidents was a collision, whereas the rest were pollution incidents occurring e.g. during fuel transfer (Figure 32). Half of the ships involved in pollution accidents were vessels other than cargo, tanker or passenger ships (Figure 33).

![Types of pollution accidents in the Baltic Sea during 2008](image1)

*Total number of accidents with pollution: 9*

![Types of ships involved in pollution accidents in the Baltic Sea during 2008](image2)

*Note that one pollution incident was a collision between two ships

*Total number of accidents with pollution: 9*
For five out of the nine accidents resulting in pollution in 2008, no information was provided on the dominating cause of the accident (Figure 34).

![Figure 34](image)

The spatial distribution of the accidents in 2008 resulting in pollution is presented in Figure 35 and some additional details of the pollution accidents are contained in Table 4.
